Package: airt (via r-universe)

October 18, 2024

Type Package

Title Evaluation of Algorithm Collections Using Item Response Theory

Version 0.2.3

Maintainer Sevvandi Kandanaarachchi <sevvandik@gmail.com>

Description An evaluation framework for algorithm portfolios using Item Response Theory (IRT). We use continuous and polytomous IRT models to evaluate algorithms and introduce algorithm characteristics such as stability, effectiveness and anomalousness (Kandanaarachchi, Smith-Miles 2020) <doi:10.13140/RG.2.2.11363.09760>.

Contents

`algo_effectiveness_crm` *Computes the actual and predicted effectiveness of a given algorithm.*

Description

This function computes the actual and predicted effectiveness of a given algorithm for different tolerance values.

Usage

```
algo_effectiveness_crm(mod, num = 1)
```

Arguments

`mod`	A fitted `mirt` model using the function `irtmodel` or `R` package `mirt`.
`num`	The algorithm number, for which the goodness of the IRT model is computed.

Value

A list with the following components:

`effective`	The `x,y` coodinates for the actual and predicted effectiveness curves for algorithm `num`.
`predictedEff`	The area under the predicted effectiveness curve.
`actualEff`	The area under the actual effectiveness curve.

Examples

```
set.seed(1)
x1 <- runif(100)
x2 <- runif(100)
x3 <- runif(100)
X <- cbind.data.frame(x1, x2, x3)
max_item <- rep(1,3)
min_item <- rep(0,3)
mod <- cirtmodel(X, max.item=max_item, min.item=min_item)
out <- algo_effectiveness_crm(mod$model, num=1)
out
```

`algo_effectiveness_poly` *Computes the actual and predicted effectiveness of a given algorithm.*

Description

This function computes the actual and predicted effectiveness of a given algorithm for different tolerance values.

Usage

```
algo_effectiveness_poly(mod, num = 1)
```

Arguments

`mod`	A fitted `mirt` model using the function `irtmodel` or `R` package `mirt`.
`num`	The algorithm number

Value

A list with the following components:

`effective`	The `x,y` coodinates for the actual and predicted effectiveness curves for algorithm `num`.
`predictedEff`	The area under the predicted effectiveness curve.
`actualEff`	The area under the actual effectiveness curve.

#'@examples set.seed(1) x1 <- sample(1:5, 100, replace = TRUE) x2 <- sample(1:5, 100, replace = TRUE) x3 <- sample(1:5, 100, replace = TRUE) X <- cbind.data.frame(x1, x2, x3) mod <- pirtmodel(X) out <- algo_effectiveness_poly(mod$model, num=1) out

`cirtmodel` *Fits a continuous IRT model.*

Description

This function fits a continuous Item Response Theory (IRT) model to the algorithm performance data. The function EstCRMitem in the R package EstCRM is updated to accommodate negative discrimination.

Usage

```
cirtmodel(df, scale = FALSE, scale.method = NULL, max.item = 1, min.item = 0)
```

Arguments

`df`	The performance data in a matrix or dataframe with good performances having high values and poor performances having low values.
`scale`	If `TRUE`, the performance data is scaled to 0-1. The default is `FALSE`.
`scale.method`	The method to scale the data. The default is `NULL`. If set to `"single"`, it scales the data to 0-1 for the full dataset. If set to `"multiple"` it scales each column/algorithm separately to 0-1. If `scale` is `FALSE`, the data is not scaled.
`max.item`	A vector with the maximum performance value for each algorithm. This can be used to inform the maximum performance value for each algorithm. Only will be used if scale is `FALSE`. Default is 1.
`min.item`	A vector with the minimum performance value for each algorithm. This can be used to inform the minimum performance value for each algorithm. Only will be used if scale is `FALSE`. Default is 0.

Value

A list with the following components:

`model`	The IRT model.
`anomalous`	A binary value for each algorithm. It is set to 1 if an algorithm is anomalous. Otherwise it is set to 0.
`consistency`	The consistency of each algorithm.
`difficulty_limit`	The difficulty limit of each algorithm. A higher difficulty limit indicates that the algorithm can tackle harder problems.

Examples

```
set.seed(1)
x1 <- runif(100)
x2 <- runif(100)
x3 <- runif(100)
X <- cbind.data.frame(x1, x2, x3)
mod <- cirtmodel(X)
```

`classification_cts` *A dataset containing classification algorithm performance data in a continuous format.*

Description

This dataset contains the performance of 10 classification algorithms on 235 datasets discussed in the paper Instance Spaces for Machine Learning Classification by M. A. Munoz, L. Villanova, D. Baatar, and K. A. Smith-Miles .

Usage

```
classification_cts
```

Format

A dataframe of 235 x 10 dimensions.

Dimension 1 Each row contains the algorithm performance of a dataset on 10 classification algorithms.

Dimensions 2 Each column contains the algorithm performance of a single algorithm.

---

effectiveness_crm *Computes the actual and predicted effectiveness of the collection of algorithms.*

Description

This function computes the actual and predicted effectiveness of the collection of algorithms for different tolerance values.

Usage

```
effectiveness_crm(model)

## S3 method for class 'effectivenesscrm'
autoplot(object, plottype = 1, ...)
```

Arguments

model	The output of the function cirtmodel.
object	For autoplot: The output of the function effectiveness_crm
plottype	For autoplot: If plottype = 1, then actual effectiveness is plotted, if plottype = 2, then predicted effectiveness is plotted. If plottype = 3, area under the actual effectiveness curve (AUAEC) is plotted against area under the predicted effectiveness curve (AUPEC).
...	Other arguments currently ignored.

Value

A list with the following components:

`effectivenessAUC`
: The area under the actual and predicted effectiveness curves.

`actcurves`
: The `x,y` coodinates for the actual effectiveness curves for each algorithm.

#'

`prdcurves`
: The `x,y` coodinates for the predicted effectiveness curves for each algorithm.

Examples

```
set.seed(1)
x1 <- runif(200)
x2 <- 2*x1 + rnorm(200, mean=0, sd=0.1)
x3 <- 1 - x1 + rnorm(200, mean=0, sd=0.1)
X <- cbind.data.frame(x1, x2, x3)
mod <- cirtmodel(X, scale = TRUE, scale.method = "multiple")
out <- effectiveness_crm(mod)
out
# For the actual effectiveness plot
autoplot(out, plottype = 1)
# For the predicted effectivness plot
autoplot(out, plottype = 2)
# For actual and predicted effectiveness plot
autoplot(out, plottype = 3)
```

`effectiveness_poly` *Computes the actual and predicted effectiveness of the collection of algorithms.*

Description

This function computes the actual and predicted effectiveness of the collection of algorithms for different tolerance values.

Usage

```
effectiveness_poly(model)

## S3 method for class 'effectivenesspoly'
autoplot(object, plottype = 1, ...)
```

Arguments

model	The output of pirtmodel function.
object	For autoplot: The output of the function effectiveness_crm
plottype	For autoplot: If plottype = 1, then actual effectiveness is plotted, if plottype = 2, then predicted effectiveness is plotted. If plottype = 3, area under the actual effectiveness curve (AUAEC) is plotted against area under the predicted effectiveness curve (AUPEC).
...	Other arguments currently ignored.

Value

A list with the following components:

effectivenessAUC
: The area under the actual and predicted effectiveness curves.

actcurves
: The x,y coodinates for the actual effectiveness curves for each algorithm.

#'

prdcurves
: The x,y coodinates for the predicted effectiveness curves for each algorithm.

Examples

```
set.seed(1)
x1 <- sample(1:5, 100, replace = TRUE)
x2 <- sample(1:5, 100, replace = TRUE)
x3 <- sample(1:5, 100, replace = TRUE)
X <- cbind.data.frame(x1, x2, x3)
mod <- pirtmodel(X)
out <- effectiveness_poly(mod)
out
# For actual effectiveness curves
autoplot(out, plottype = 1)
# For predicted effectiveness curves
autoplot(out, plottype = 2)
# For Actual and Predicted Effectiveness (AUAEC, AUPEC)
autoplot(out, plottype = 3)
```

---

heatmaps_crm *Function to produce heatmaps from a continuous IRTmodel*

Description

This function makes a dataframe from the continuous IRTmodel the autoplot function produces the heatmaps.

Usage

```
heatmaps_crm(model, thetarange = c(-6, 6))

## S3 method for class 'heatmapcrm'
autoplot(
  object,
  xlab = "Theta",
  nrow = 2,
  ratio = 1,
  col_scheme = "plasma",
  ...
)
```

Arguments

model	Output from the function cirtmodel.
thetarange	The range for theta, default from -6 to 6.
object	For autoplot: output of heatmaps_crm function.
xlab	For autoplot: xlabel.
nrow	For autoplot: number of rows of heatmaps to plot.
ratio	For autoplot: ratio for coord_fixed in ggplot.
col_scheme	For autoplot: the color scheme for heatmaps. Default value is plasma.
...	Other arguments currently ignored.

Value

Dataframe with output probabilities from the IRT model for all algorithms, an object of class heatmapcrm.

Examples

```
data(classification_cts)
model <- cirtmodel(classification_cts)
obj <- heatmaps_crm(model)
head(obj$df)
autoplot(obj)
```

---

latent_trait_analysis *Performs the latent trait analysis*

Description

This function performs the latent trait analysis of the datasets/problems after fitting a continuous IRT model. It fits a smoothing spline to the points to compute the latent trait. The autoplot function plots the latent trait and the performance.

Usage

```
latent_trait_analysis(
  df,
  scale = FALSE,
  scale.method = NULL,
  max.item = 1,
  min.item = 0,
  paras,
  epsilon = 0.01
)

## S3 method for class 'latenttrait'
autoplot(
  object,
  xlab = "Problem Difficulty",
  ylab = "Performance",
  plottype = 1,
  nrow = 2,
  se = TRUE,
  ratio = 3,
  ...
)
```

Arguments

df	The performance data in a matrix or dataframe with good performances having high values and poor performances having low values.
scale	If TRUE, the performance data is scaled to 0-1. The default is FALSE.
scale.method	The method to scale the data. The default is NULL. If set to "single", it scales the data to 0-1 for the full dataset. If set to "multiple" it scales each column/algorithm separately to 0-1. If scale is FALSE, the data is not scaled.
max.item	A vector with the maximum performance value for each algorithm. This can be used to inform the maximum performance value for each algorithm. Only will be used if scale is FALSE. Default is 1.
min.item	A vector with the minimum performance value for each algorithm. This can be used to inform the minimum performance value for each algorithm. Only will be used if scale is FALSE. Default is 0.
paras	The parameters from fitting cirtmodel.
epsilon	A value defining good algorithm performance. If epsilon = 0, then only the best algorithm is considered. A default
object	For autoplot: the output of the function latent_trait_analysis.
xlab	For autoplot: the xlabel.
ylab	For autoplot: the ylabel.
plottype	For autoplot: plottype = 1 for all algorithm performances in a single plot, plottype = 2 for using facet_wrap to plot individual algorithms, plottype = 3 to plot the smoothing splines and plottype = 4 to plot strengths and weaknesses.

nrow	For autoplot: If plottype = 2, the number of rows for facet_wrap.
se	For autoplot: for plotting splines with standard errors.
ratio	For autoplot: for plotting strengths and weaknesses, ratio between x and y axis.
...	Other arguments currently ignored.

Value

A list with the following components:

crmtheta	The problem trait output computed from the R package EstCRM.
strengths	The strengths of each algorithm and positions on the latent trait that they performs well.
longdf	The dataset in long format of latent trait occupancy.
plt	The ggplot object showing the fitted smoothing splines.
widedf	The dataset in wide format with latent trait.
thetas	The easiness of the problem set instances.
weakness	The weaknesses of each algorithm and positions on the latent trait that they performs poorly.

Examples

```
# This is a dummy example.
set.seed(1)
x1 <- runif(200)
x2 <- 2*x1 + rnorm(200, mean=0, sd=0.1)
x3 <- 1 - x1 + rnorm(200, mean=0, sd=0.1)
X <- cbind.data.frame(x1, x2, x3)
max_item <- rep(max(x1, x2, x3),3)
min_item <- rep(min(x1, x2, x3),3)
mod <- cirtmodel(X, max.item=max_item, min.item=min_item)
out <- latent_trait_analysis(X, min.item= min_item, max.item = max_item, paras = mod$model$param)
out
# To plot performance against the problem difficulty
autoplot(out)
# To plot individual panels
autoplot(out, plottype = 2)
# To plot smoothing splines
autoplot(out, plottype = 3)
# To plot strengths and weaknesses
autoplot(out, plottype = 4)
```

make_polyIRT_data *Converts continuous performance data to polytomous data with 5 categories.*

Description

This function converts continous performance data to polytomous data with 5 categories

Usage

```
make_polyIRT_data(df, method = 1)
```

Arguments

df	The input data in a dataframe or a matrix
method	If 1, then the data is an accuracy measure between 0 and 1. If 2, then the performance data is possibly has a bigger range. So we divide it into 5 equal bins to make it polytomous.

Value

The polytomous data frame.

Examples

```
set.seed(1)
x1 <- runif(500)
x2 <- runif(500)
x3 <- runif(500)
x <- cbind(x1, x2, x3)
xout <- make_polyIRT_data(x)
```

model_goodness_crm *Computes the goodness of IRT model for all algorithms.*

Description

This function computes the goodness of the IRT model for all algorithms for different goodness tolerances.

Usage

```
model_goodness_crm(model)

## S3 method for class 'modelgoodnesscrm'
autoplot(object, ...)
```

Arguments

model	The output of function cirtmodel.
object	For autoplot: The output of model_goodness_crm.
...	Other arguments currently ignored.

Value

A list with the following components:

goodnessAUC	The area under the model goodness curve for each algorithm.
curves	The x,y coordinates for the model goodness curves for each algorithm.
residuals	The residuals for each algorithm using the AIRT model.

Examples

```
set.seed(1)
x1 <- runif(200)
x2 <- 2*x1 + rnorm(200, mean=0, sd=0.1)
x3 <- 1 - x1 + rnorm(200, mean=0, sd=0.1)
X <- cbind.data.frame(x1, x2, x3)
mod <- cirtmodel(X, scale = TRUE, scale.method = "multiple")
out <- model_goodness_crm(mod)
out
autoplot(out)
```

---

model_goodness_for_algo_crm

Computes the goodness of IRT model for a given algorithm.

Description

This function computes the goodness of the IRT model for a given algorithm for different goodness tolerances.

Usage

```
model_goodness_for_algo_crm(mod, num = 1)
```

Arguments

mod	A fitted mirt model using the function irtmodel or R package mirt.
num	The algorithm number, for which the goodness of the IRT model is computed.

Value

A list with the following components:

xy	The x values denote the goodness tolerances. The y values denote the model goodness.
auc	The area under the model goodness curve.
residuals	The different between actual and fitted performance values.

Examples

```
set.seed(1)
x1 <- runif(100)
x2 <- runif(100)
x3 <- runif(100)
X <- cbind.data.frame(x1, x2, x3)
max_item <- rep(1,3)
min_item <- rep(0,3)
mod <- cirtmodel(X, max.item=max_item, min.item=min_item)
out <- model_goodness_for_algo_crm(mod$model, num=1)
out
```

---

model_goodness_for_algo_poly

Computes the goodness of the IRT model fit for a given algorithm.

Description

This function computes the goodness of the IRT model fit for a given algorithm using the empirical cumulative distribution function of errors.

Usage

```
model_goodness_for_algo_poly(mod, num = 1)
```

Arguments

mod	A fitted mirt model using the function irtmodel or R package mirt.
num	The algorithm number

Value

A list with the following components:

xy	The x values denote the error tolerances. The y values denotes its empirical cumulative distribution function.
auc	The area under the CDF.
mse	The mean squared error.

Examples

```
set.seed(1)
x1 <- sample(1:5, 100, replace = TRUE)
x2 <- sample(1:5, 100, replace = TRUE)
x3 <- sample(1:5, 100, replace = TRUE)
X <- cbind.data.frame(x1, x2, x3)
mod <- pirtmodel(X)
out <- model_goodness_for_algo_poly(mod$model, num=1)
out
```

---

model_goodness_poly *Computes the goodness of IRT model for all algorithms.*

Description

This function computes the goodness of the IRT model for all algorithms using the empirical cumulative distribution function of errors.

Usage

```
model_goodness_poly(model)

## S3 method for class 'modelgoodnesspoly'
autoplot(object, ...)
```

Arguments

model	The output from pirtmodel function.
object	For autoplot: The output of the model_goodness_poly function.
...	Other arguments currently ignored.

Value

A list with the following components:

goodnessAUC	The area under the model goodness curve for each algorithm.
mse	The mean squared error.
curves	The x,y coodinates for the model goodness curves for each algorithm.

Examples

```
set.seed(1)
x1 <- sample(1:5, 100, replace = TRUE)
x2 <- sample(1:5, 100, replace = TRUE)
x3 <- sample(1:5, 100, replace = TRUE)
X <- cbind.data.frame(x1, x2, x3)
```

```
mod <- pirtmodel(X)
out <- model_goodness_poly(mod)
out
autoplot(out)
```

`pirtmodel` *Fits a polytomous IRT model.*

Description

This function fits a polytomous Item Response Theory (IRT) model using the R package mirt to the algorithm performance data.

Usage

```
pirtmodel(dat, ncycle = NULL, vpara = TRUE)
```

Arguments

`dat`	The performance data in a matrix or dataframe.
`ncycle`	The number of cycles for `mirt`. The default is 500.
`vpara`	It `TRUE` the `verbose` parameter for the `mirt` would be set to true.

Value

A list with the following components:

`model`	The IRT model using the R package `mirt`.
`anomalous`	A binary value for each algorithm. It is set to 1 if an algorithm is anomalous. Otherwise it is set to 0.
`consistency`	The consistency of each algorithm.
`difficulty_limit`	The difficulty limits for each algorithm. A higher threshold indicates that the algorithm can tackle harder problems.

References

R. Philip Chalmers (2012). mirt: A Multidimensional Item Response Theory Package for the R Environment. Journal of Statistical Software, 48(6), 1-29. doi:10.18637/jss.v048.i06

Examples

```
set.seed(1)
x1 <- sample(1:5, 100, replace = TRUE)
x2 <- sample(1:5, 100, replace = TRUE)
x3 <- sample(1:5, 100, replace = TRUE)
X <- cbind.data.frame(x1, x2, x3)
mod <- pirtmodel(X)
```

tracelines_poly *Function to plot tracelines from a polytomous IRTmodel*

Description

This function makes a dataframe from the polytomous IRTmodel. The autoplot function can be used to plot trace lines

Usage

```
tracelines_poly(model)

## S3 method for class 'tracelinespoly'
autoplot(
  object,
  xlab = "Theta",
  ylab = "Probability",
  nrow = 2,
  title = "Tracelines",
  ...
)
```

Arguments

model	Output from the function pirtmodel.
object	For autoplot: output of tracelines_poly function.
xlab	For autoplot: xlabel.
ylab	For autoplot: ylabel.
nrow	For autoplot: number of rows of heatmaps to plot.
title	For autoplot: the title for the plot.
...	Other arguments currently ignored.

Value

Dataframe with output probabilities from the IRT model for all algorithms, an object of the class tracelinespoly.

Examples

```
data(classification_poly)
mod <- pirtmodel(classification_poly)
obj <- tracelines_poly(mod)
head(obj$df)
autoplot(obj)
```
